# What is pendulum ?

A pendulum is a body suspended from a fixed point so that it can swing back and forth under the influence of gravity. The time interval of a pendulum's complete back-and-forth movement is constant.

# Simple Pendulum

A simple pendulum consists of a mass  $m$  hanging from a string of length  $L$  and fixed at a pivot point  $P$ . When displaced to an initial angle and released, the pendulum will swing back and forth with periodic motion. ... with being the natural frequency of the motion.

# Compound Pendulum

- **Definition:** A rigid body of any shape, capable of oscillating about a horizontal axis passing through it in a vertical plane is called a **Compound Pendulum**.
- **Centre of Suspension:** *The point through which the vertical plane passing through the centre of gravity of the pendulum meets the axis of rotation.*
- The distance between the point of suspension and the C.G. of the pendulum is called the **length of the pendulum**.
- **Equation of motion of the compound pendulum:**
- Let an arbitrary shaped rigid body of mass  $m$  is capable of oscillating freely about a horizontal axis passing through it perpendicular to its plane.

$$T = 2\pi \sqrt{\frac{I}{mgl}}$$

The time period of a physical pendulum is given by  $T = 2\pi \sqrt{\frac{I}{mgl}}$

. Where  $m$  = mass of the pendulum  $I$  = moment of inertia about the axis of suspension,  $l$  = distance of centre of mass of bob from the centre of suspension. Calculate the change in time period when temperature changes by  $\Delta T$ . The coefficient of linear expansion of the material of pendulum is  $\alpha$ .

## **Why compound pendulum is better than simple pendulum ?**

**A simple pendulum, the only physical property of the pendulum that affect its period is its length. The mass of the object does not affect the period. In a compound pendulum, the object's mass and how that mass is distributed both play a role in determining the period.**
